Fundamentals of Accelerator Physics

Lecture 9: Introduction to RF accelerators

September 26, 2018

Vladimir N. Litvinenko

Acknowledgement

Next three lectures use some materials from courses on RF and Superconducting RF (SRF) accelerators taught by Prof. S. Belomestnykh at SBU/BNL and USPAS, which can be found on the following websites:

http://case.physics.stonybrook.edu/index.php/Courses:_P554_Fundamentals_of_Accelerator_Physics,_Spring_2014

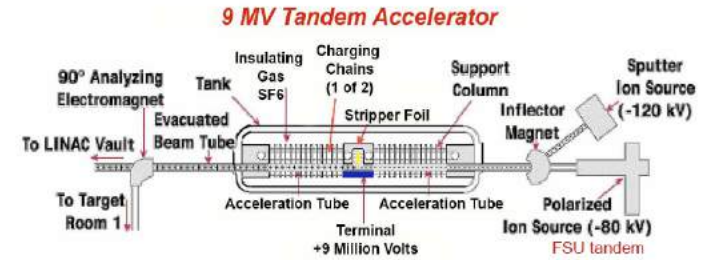

<http://case.physics.stonybrook.edu/index.php/CASE:Courses>

<https://sites.google.com/site/srfsbu11/>

<http://uspas.fnal.gov/materials/materials-table.shtml>

I added additional material as needed

Linear accelerators: from electrostatic to RF

Can one gain the energy again and again by passing through a DC accelerating gap?

Electrostatic: what is the limit ?

Maxwell equations and energy conservation law!

$$\Delta E = e \oint \vec{E} \cdot d\vec{l} = -\frac{e}{c} \frac{\partial}{\partial t} \left(\int \vec{H} \cdot d\vec{s} \right)$$

DC

$$\Delta E = e \oint \vec{E} \cdot d\vec{l} = 0$$

$$\vec{E} = -\vec{\nabla} \varphi \rightarrow E(\vec{r}) = E(0) - e\varphi(\vec{r})$$

Can not cheat the Maxwell equations

Induction linacs: linear betatrons

$$\oint \vec{E} \cdot d\vec{l} = -\frac{\partial}{\partial t} \left(\int \vec{H} \cdot d\vec{s} \right)$$

- Useful for high power and high current beams
- Have limited accelerating field
- By nature are pulsed, with relatedly low rep-rate (kHz)

How RF accelerator works

- It has oscillating (typically sinusoidal in time) longitudinal (along the particle's trajectory) electric field
- It also has longitudinal structure (cells) which alternates the direction of the field
- When particle propagates through the RF accelerator, the field direction in each cell is synchronized with the particle arrival and the effect from all cells is added coherently

$$\frac{dE}{dt} = e\vec{E} \cdot \vec{v} \quad \rightarrow \quad \text{sign}(\vec{E} \cdot \vec{v}) = \text{const}$$

Wideröe's linac: $\beta = v/c$ is changing

Electron linac

$$\beta = v/c \sim 1$$

Wave-form in 5-cell cavity

How $\beta=1$ RF linac works? Example of 5-cell cavity

Simple things to remember

- Acceleration in DC electrostatic is limited to the difference in terminal potential (e.g. voltage between the ground and the cathode)
- RF linear accelerators (RF linacs or simply linacs) are not limited in beam energy
- In RF linacs, the coherent addition/subtraction of the energy gain from cell to cell happens by design: period of the electric field oscillation is matched to the travel time of electron between the cells.
- Accurate synchronization of RF linac is important task for any linear accelerator

A bit of EM and conducting media

$$\vec{j} = \sigma \vec{E};$$

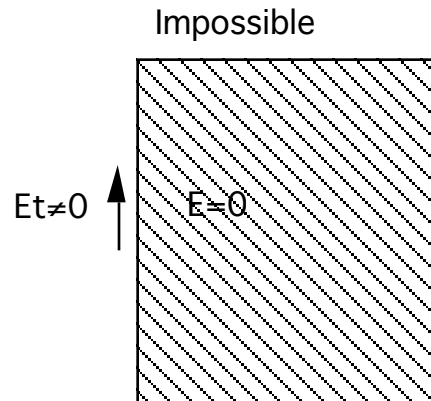

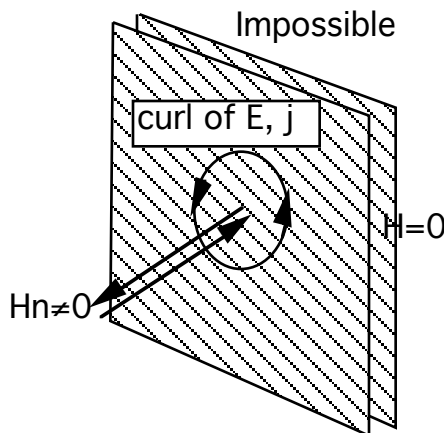

- Assuming oscillating field we can use Coulomb gauge for EM field

$$\vec{A} = \text{Re} \left\{ \vec{A}(\vec{r}) \exp(i\omega t) \right\}; \varphi = 0;$$

$$\vec{E} = -\frac{1}{c} \frac{\partial \vec{A}}{\partial t}; \quad \vec{B} = \text{curl} \vec{A}.$$

$$|\vec{H}| \propto \left| \frac{(\alpha + i\beta)}{k_o} \right| |\vec{E}| = \left| \sqrt{1 + \frac{4\pi i\sigma}{\omega}} \right| |\vec{E}|$$

$$\sigma \rightarrow \infty$$

Boundary conditions

- We are considering oscillating EM fields in RF structures
- RF structures are built from highly conducting material, both to contain EM field inside and to provide low losses
- In first approximation we can consider an ideal boundary conditions and take finite conductivity as a perturbation later
- Q-factor: $Q_{\text{room temp}} \sim 10^3-10^5$, $Q_{\text{SRF}} \sim 10^9-10^{10}$

$$\vec{A} = \text{Re} \left\{ \vec{A}(\vec{r}) \exp(i\omega t - \alpha t) \right\};$$

$$\alpha = \frac{2\pi\omega}{Q}$$

$$\vec{E} = \vec{n}(\vec{n}\vec{E}) + \vec{E}_{//}; \vec{B} = \vec{n}(\vec{n}\vec{B}) + \vec{B}_{//};$$

Waveguides

Rectangular

Circular

$$\left(\Delta - \frac{1}{c^2} \frac{\partial^2}{\partial t^2} \right) \vec{A} = 0; \quad \Delta \equiv \vec{\nabla}^2 = \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial z^2};$$

$$\vec{A} = \text{Re} \left\{ \vec{A}(\vec{r}_\perp) \exp(i(\omega t - k_z z)) \right\};$$

$$\vec{\nabla}_\perp^2 \vec{A} + (k_o^2 - k_z^2) \vec{A} = 0; \quad k_o = \frac{\omega}{c}.$$

$$\vec{\nabla}_\perp^2 \equiv \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} = \frac{1}{r} \frac{\partial}{\partial r} \left(r \frac{\partial}{\partial r} \right) + \frac{1}{r^2} \frac{\partial^2}{\partial \theta^2}.$$

At the surfaces

$$\vec{n} \times \vec{E}|_s = 0; \quad \vec{n} \cdot \vec{B} = 0 \rightarrow E_z|_s = 0; \quad \left. \frac{\partial B_z}{\partial n} \right|_s = 0$$

TE and TM waves

Rectangular

- There is simplification
 - The modes are divided into two types: TE (transverse electric) and TM (transverse magnetic)

Circular

$$\vec{E} = \vec{E}_z + \vec{E}_\perp; \vec{B} = \vec{B}_z + \vec{B}_\perp; \vec{A}_z \equiv \hat{z}A_z;$$

$$\vec{\nabla} \times \vec{E} = ik_o \vec{B}; \vec{\nabla} \times \vec{B} = -ik_o \vec{E}; \Rightarrow$$

$$ik_z \vec{E}_\perp + ik_o [\hat{z} \times \vec{B}_\perp] = \vec{\nabla}_\perp \vec{E}_z;$$

$$ik_z \vec{B}_\perp - ik_o [\hat{z} \times \vec{E}_\perp] = \vec{\nabla}_\perp \vec{B}_z;$$

At the surfaces

$$\vec{n} \times \vec{E}|_s = 0; \vec{n} \cdot \vec{B} = 0 \rightarrow E_z|_s = 0; \left. \frac{\partial B_z}{\partial n} \right|_s = 0$$

$$TM : B_z \equiv 0; E_z|_s = 0;$$

$$TE : E_z \equiv 0; B_z|_s = 0;$$

- Last two equations indicated that E_z and B_z fully determine transverse component of the EM field
- It means that we can always consider a linear combination of the fields with $E_z = 0$ everywhere (TE) and $B_z = 0$ everywhere (TM)
- Naturally, when we interested in accelerating particles, we will need TM mode with $E_z \neq 0$.

$$\vec{B}_\perp = \pm \frac{k_z}{k_o} [\hat{z} \times \vec{E}_\perp] \quad \text{for both TE and TM modes}$$

$$TM: \vec{E}_\perp = \vec{\nabla}_\perp \psi_1(\vec{r}_\perp); TE: \vec{B}_\perp = \vec{\nabla}_\perp \psi_2(\vec{r}_\perp);$$

Cut-off frequency

Rectangular

- EM field is a linear combination of modes with $E_z = 0$ everywhere (TE) and $B_z = 0$ everywhere (TM)

At the surfaces

$$\vec{n} \times \vec{E}|_s = 0; \vec{n} \cdot \vec{B} = 0 \rightarrow E_z|_s = 0; \left. \frac{\partial B_z}{\partial n} \right|_s = 0$$

$$\vec{B}_\perp = \pm \frac{k_z}{k_o} [\hat{z} \times \vec{E}_\perp] \quad \text{for both TE and TM modes}$$

$$\text{TM: } \vec{E}_\perp = \vec{\nabla}_\perp \psi_1(\vec{r}_\perp); \quad \text{TE: } \vec{B}_\perp = \vec{\nabla}_\perp \psi_2(\vec{r}_\perp);$$

$$\vec{\nabla}_\perp^2 \psi + (k_o^2 - k_z^2) \psi = 0 + \text{boundary conditions}$$

Different boundary conditions for TE and TM modes
In general case we need to find eigen function (modes)

Circular

$$\text{TM: } B_z \equiv 0; \quad E_z|_s = 0;$$

$$\text{TE: } E_z \equiv 0; \quad B_z|_s = 0;$$

$$\text{TM: } \psi|_s = 0; \quad \text{TE: } \left. \frac{\partial \psi}{\partial n} \right|_s = 0.$$

$$\vec{\nabla}_\perp^2 \psi_\lambda + \gamma_\lambda^2 \psi_\lambda = 0;$$

$$\lambda = 1, 2, 3, \dots$$

Cut-off

$$k_{z,\lambda}^2 = k_o^2 - \gamma_\lambda^2 > 0$$

Below cut-off

$$\omega < \omega_{\text{cut-off}}$$

evanescent wave: $k_z = \pm i \sqrt{\omega_{\text{cut-off}}^2 - \omega^2} = \pm i \kappa_z$

Exp decay

$$\psi = \psi_0 e^{\pm \kappa_z z}$$

frequency

$$k_{o,\text{min}} = \gamma_\lambda \rightarrow \omega_{\text{cut-off}} = c \gamma_\lambda$$

Cut-off frequency

Rectangular

$$\left(\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} \right) \psi + \gamma_{mn}^2 \psi = 0$$

$$TE : \psi^{TE}_{mn} = \psi_o \cos k_m x \cos k_n y; \quad m + n \geq 1;$$

$$TM : \psi^{TM}_{mn} = \psi_o \sin k_m x \sin k_n y; \quad m \geq 1; n \geq 1;$$

$$k_m = \pi \frac{m}{a}; k_n = \pi \frac{n}{b}; \gamma_{mn}^2 = k_m^2 + k_n^2.$$

*Different boundary conditions
for TE and TM modes*

$$TM : \psi|_s = 0; \quad TE : \left. \frac{\partial \psi}{\partial n} \right|_s = 0.$$

Circular

$$\frac{1}{r} \frac{\partial}{\partial r} \left(r \frac{\partial \psi}{\partial r} \right) + \frac{1}{r^2} \frac{\partial^2 \psi}{\partial \theta^2} + \gamma_{mn}^2 \psi = 0$$

$$\psi_{mn} = \varphi_{mn}(r) e^{in\theta} \Rightarrow r \frac{\partial}{\partial r} \left(r \frac{\partial \psi_m}{\partial r} \right) + (r^2 \gamma_{mn}^2 - n^2) = 0$$

$$\varphi_{mn} = J_n(\gamma_{mn} r)$$

Lowest cut-off frequency

Rectangular

$$TE : a > b; m = 1; n = 0; \omega_{cut-off} = \frac{\pi c}{a};$$

$$TM : m = 1; n = 1; \omega_{cut-off} = \frac{\pi c}{a} \sqrt{1 + \frac{a^2}{b^2}}.$$

Circular

$$TM : J_0(\gamma_{01} R) = 0 \rightarrow \gamma_{01} \cong \frac{2.40483..}{R}; \omega_{cut-off} \cong \frac{2.40 c}{R};$$

$$TE : J_1(\gamma_{11} R) = 0 \rightarrow \gamma_{11} \cong \frac{1.84118....}{R}; \omega_{cut-off} \cong \frac{1.84 c}{R}.$$

Modes in rectangular waveguide

RF cavities

are designed to confine the EM field inside: It means that they operate at frequency below cut-off of the beam-pipes attached to them

RF Cavity Modes:

the lowest accelerating is TM_{010} mode

- Fields in the cavity are solutions of the equation
- Subject to the boundary conditions $\hat{n} \times \mathbf{E} = 0, \hat{n} \cdot \mathbf{H} = 0$
- Two extra surfaces ($z=0$ and $z=d$): but this is no problem for TM mode
- An infinite number of solutions (eigen modes) belong to two families of modes with different field structure and eigen frequencies: TE modes have only transverse electric fields, TM modes have only transverse magnetic fields.
- One needs longitudinal electric field for acceleration, hence the lowest frequency TM_{010} mode is used.
- For the pillbox cavity w/o beam tubes
- Note that frequency does not depend of the cavity length! But only its radius.

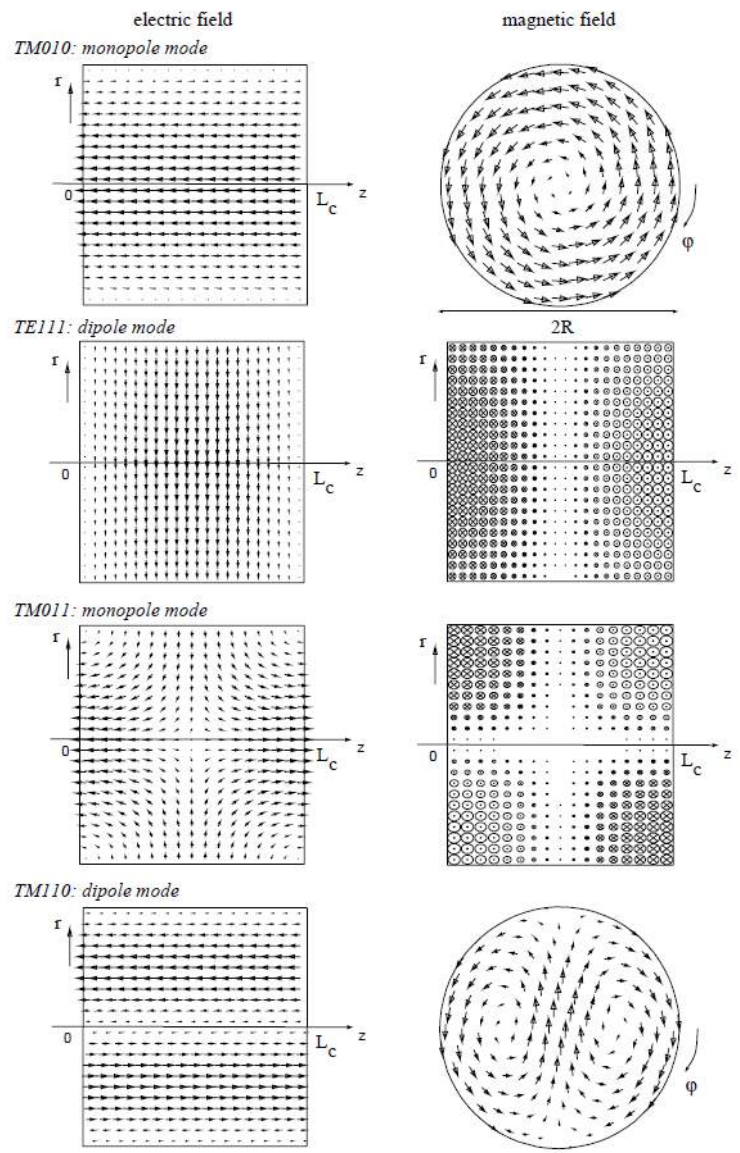

$$\left(\nabla^2 - \frac{1}{c} \frac{\partial^2}{\partial t^2} \right) \begin{Bmatrix} \mathbf{E} \\ \mathbf{H} \end{Bmatrix} = 0$$

$$E_z = E_0 J_0 \left(\frac{2.405r}{R} \right) e^{i\omega t}$$
$$H_\phi = -iE_0 J_1 \left(\frac{2.405r}{R} \right) e^{i\omega t}$$
$$\omega_{010} = \frac{2.405c}{R}, \lambda_{010} = 2.61R$$

Fundamental and high order modes (HOMs)

Eigenmodes in a Pill-box cavity

$$TM : \varphi_{mnl} = J_n(\gamma_{mn}r) \cos k_{z,l}z; \quad k_{z,l} = l \frac{\pi}{d}; \quad J_n(\gamma_{mn}R) = 0;$$

$$\omega_{res} = c \sqrt{\gamma_{mn}^2 + l^2 \frac{\pi^2}{d^2}}; \quad l = 0, 1, 2, \dots$$

$$TE : \varphi_{mnl} = J_n(\kappa_{mn}r) \sin k_{z,l}z; \quad k_{z,l} = l \frac{\pi}{d}; \quad J'_n(\kappa_{mn}R) = 0;$$

$$\omega_{res} = c \sqrt{\kappa_{mn}^2 + l^2 \frac{\pi^2}{d^2}}; \quad l = 1, 2, \dots$$

Accelerating voltage & transit time

- Assuming charged particles moving along the cavity axis, one can calculate accelerating voltage as

$$V_c = \left| \int_{-\infty}^{\infty} E_z(\rho=0, z) e^{i\omega_0 z/\beta c} dz \right|$$

For the pillbox cavity one can integrate this analytically:

$$V_c = E_0 \left| \int_0^d e^{i\omega_0 z/\beta c} dz \right| = E_0 d \frac{\sin\left(\frac{\omega_0 d}{2\beta c}\right)}{\frac{\omega_0 d}{2\beta c}} = E_0 d \cdot T$$

where T is the transit time factor.

- To get maximum acceleration:

$$T_{transit} = t_{exit} - t_{enter} = \frac{T_0}{2} \Rightarrow d = \beta\lambda/2 \Rightarrow V_c = \frac{2}{\pi} E_0 d$$

Thus for the pillbox cavity $T = 2/\pi$.

- The accelerating field E_{acc} is defined as $E_{acc} = V_c/d$. Unfortunately the cavity length is not easy to specify for shapes other than pillbox so usually it is assumed to be $d = \beta\lambda/2$. This works OK for multi-cell cavities, but poorly for single-cell ones.

Multicell cavities: coupled oscillators

- Several cells can be connected together to form a multicell cavity.
- Coupling of TM_{010} modes of the individual cells via the iris (primarily electric field) causes them to split:

Multicell cavities (2)

- The split mode forms a passband of closely spaced modes equal in number to the number of cells.

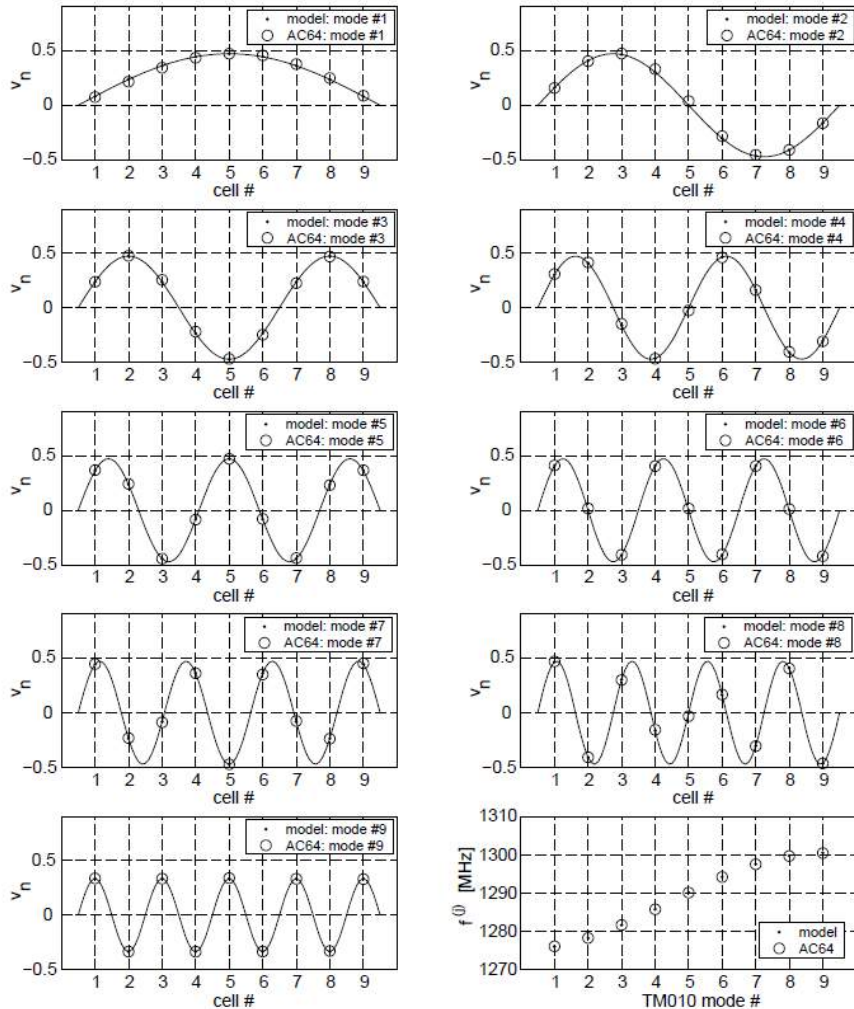

- The frequency of the n -th mode can be calculated from the dispersion formula

$$\left(\frac{f_n}{f_0}\right)^2 = 1 + 2k \left[1 - \cos\left(\frac{n\pi}{N}\right) \right]$$

where N is the number of cells,
 $n = 1 \dots N$ is the mode number.

Multicell cavities (2)

- Figure shows an example of calculated eigenmodes amplitudes in a 9-cell TESLA cavity compared to the measured amplitude profiles. Also shown are the calculated and measured eigenfrequencies.
- A longer cavity with more cells has more modes in the same frequency range, hence the reduction in frequency difference between adjacent modes. The number of cells is usually a result of the accelerating structure optimization.
- The accelerating mode for SC cavities is usually the **p**-mode, which has the highest frequency for electrically coupled structures.
- The same considerations are true for HOMs.

What we learned

- Resonant modes in a cavity resonator belong to two families: TE and TM.
- There is an infinite number of resonant modes.
- The lowest frequency TM mode is usually used for acceleration.
- All other modes (HOMs) are considered parasitic as they can harm the beam.
- Several figures of merits are used to characterize accelerating cavities: main are accelerating voltage, transit time and Q-factor.
- In a multi-cell cavity every mode splits into a pass-band.
- The number of modes in each pass-band is equal to the number of cavity cells.
- The width of the pass-band is determined by the cell-to-cell coupling.
- Accelerating cavities operate at frequency below the cut-off frequency of vacuum pipes connected to them. The RF field decay exponentially along the pipes and reduces to a negligible level at length \sim few beam-pipe radii (assuming $R \ll \lambda_{\text{RF}}$)
- Coaxial lines and rectangular waveguides are commonly used in RF systems for power delivery to cavities
- Homework is posted on the website this evening: due in one week, October 3
