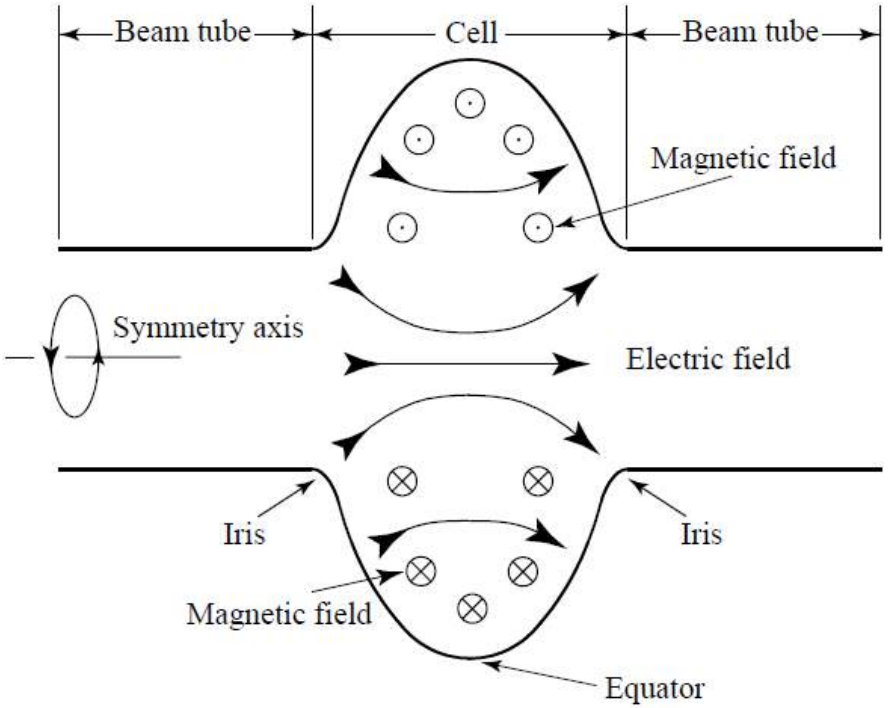
Fundamentals of Accelerator Physics

Lecture 9: Introduction to RF accelerators

September 26, 2018

Vladimir N. Litvinenko



http://case.physics.stonybrook.edu/index.php/PHY554_fall_2018

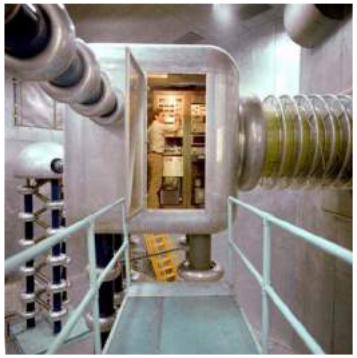
Acknowledgement

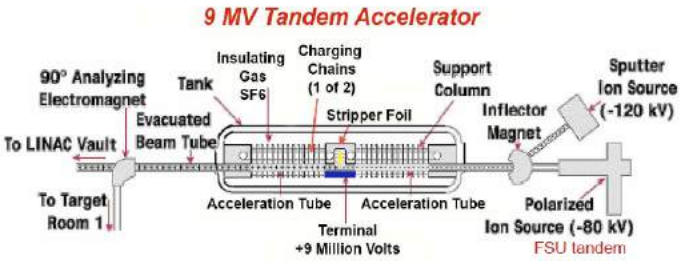
Next three lectures use some materials from courses on RF and Superconducting RF (SRF) accelerators taught by Prof. S. Belomestnykh at SBU/BNL and USPAS, which can be found on the following websites:

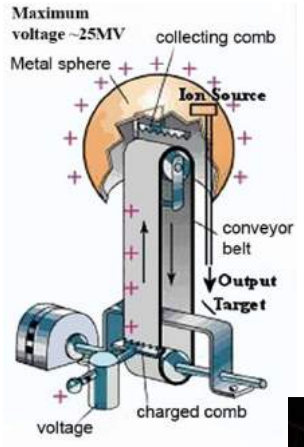
http://case.physics.stonybrook.edu/index.php/Courses:_P554_Fundamentals_of_Accelerator_Physics,_Spring_2014
http://case.physics.stonybrook.edu/index.php/CASE:Courses
https://sites.google.com/site/srfsbu11/
http://uspas.fnal.gov/materials/materials-table.shtml

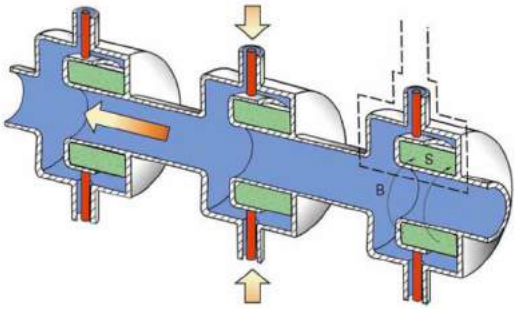
I added addition material as needed

Linear accelerators: from electrostatic to RF







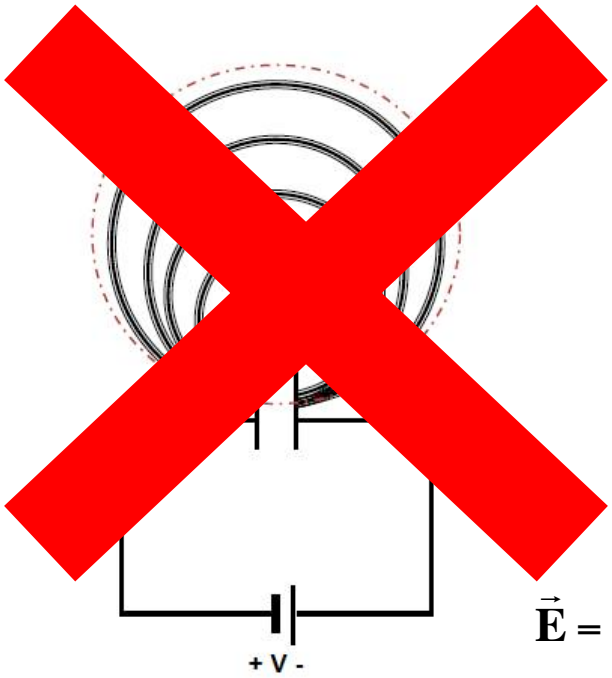


Can one gain the energy again and again by passing through a DC accelerating gap?

Electrostatic: what is the limit ?

Maxwell equations and energy conservation law!

$$\Delta E = e\oint \vec{\mathbf{E}}\cdot d\vec{l} = -\frac{e}{c}\frac{\partial}{\partial t}\left(\int \vec{\mathbf{B}}\cdot d\vec{s}\right)$$



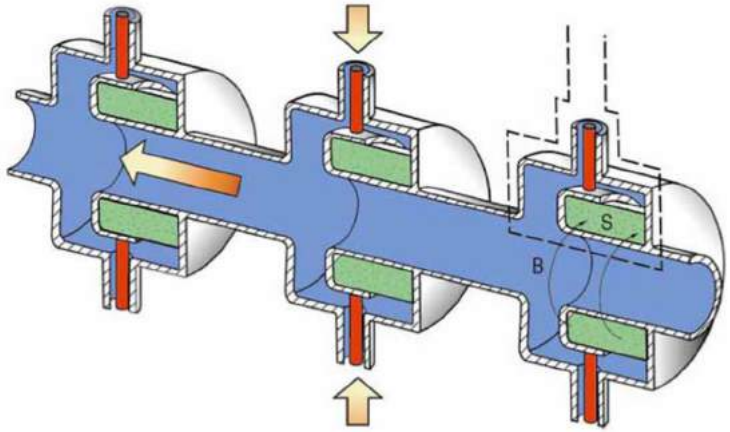
DC

$$\Delta E = e\oint \vec{\mathbf{E}}\cdot d\vec{l} = 0$$

$$\vec{\mathbf{E}} = -\vec{\nabla}\varphi \quad \rightarrow \quad E(\vec{r}) = E(0) - e\varphi(\vec{r})$$

Can not cheat the Maxwell equations

Induction linacs: linear betatrons

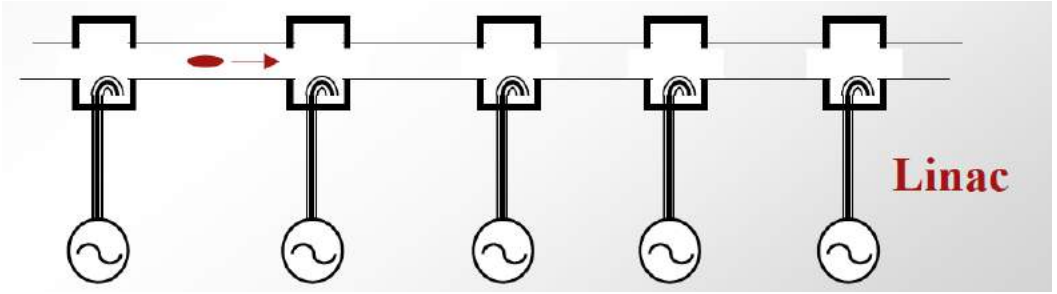


$$\oint \vec{\mathbf{E}} \cdot d\vec{l} = -\frac{\partial}{\partial t}\left(\int \vec{\mathbf{H}} \cdot d\vec{s} \right)$$

- Useful for high power and high current beams
- Have limited accelerating field
- By nature are pulsed, with relatedly low rep-rate (kHz)

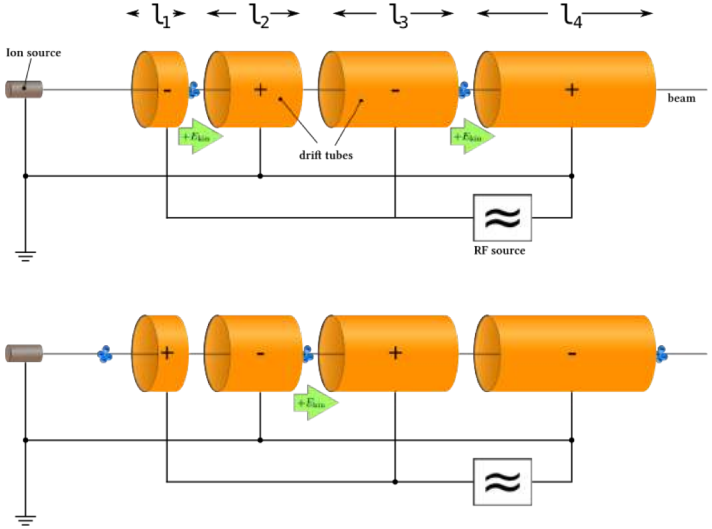
How RF accelerator works

- It has oscillating (typically sinusoidal in time) longitudinal (along the particle's trajectory) eclectic field
- It also has longitudinal structure (cells) which alternates the direction of the filed
- When particle propagates through the RF accelerator, the field direction in each cell is synchronized with the particle arrival and the effect from all cells is added coherently

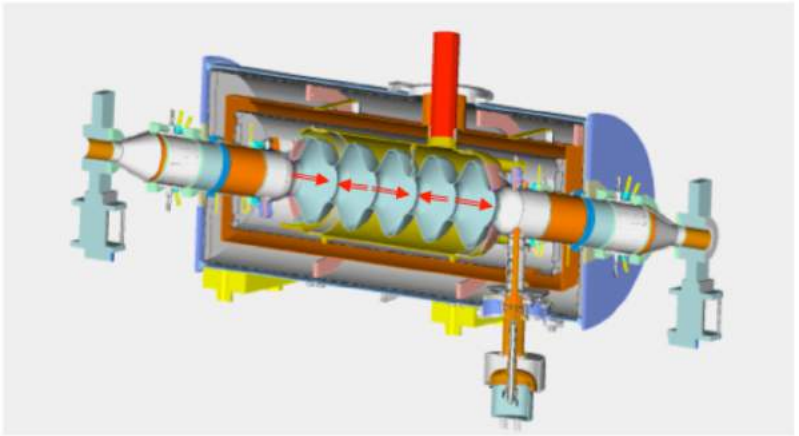


$$\frac{dE}{dt} = e\vec{\mathbf{E}}\cdot\vec{\mathrm{v}} \quad \rightarrow \mathrm{sign}(\vec{\mathbf{E}}\cdot\vec{\mathrm{v}})=\mathrm{const}$$

Wideröe's linac: $\beta=v/c$ is changing

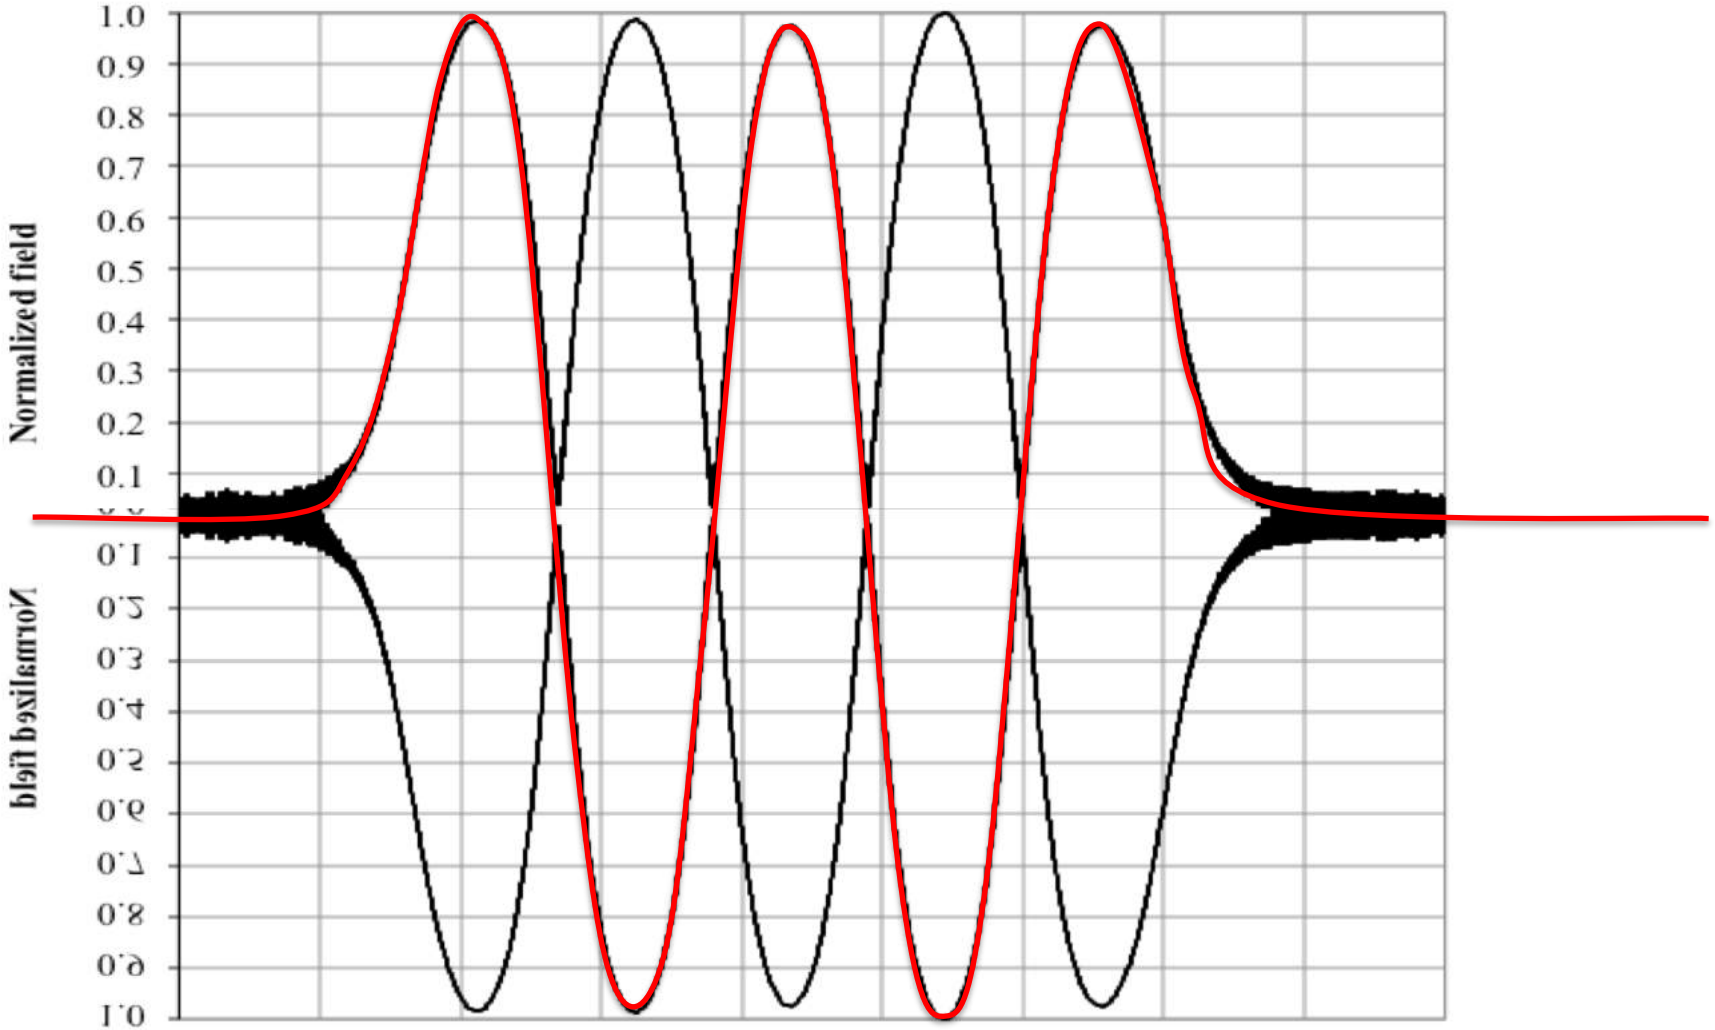


Electron linac

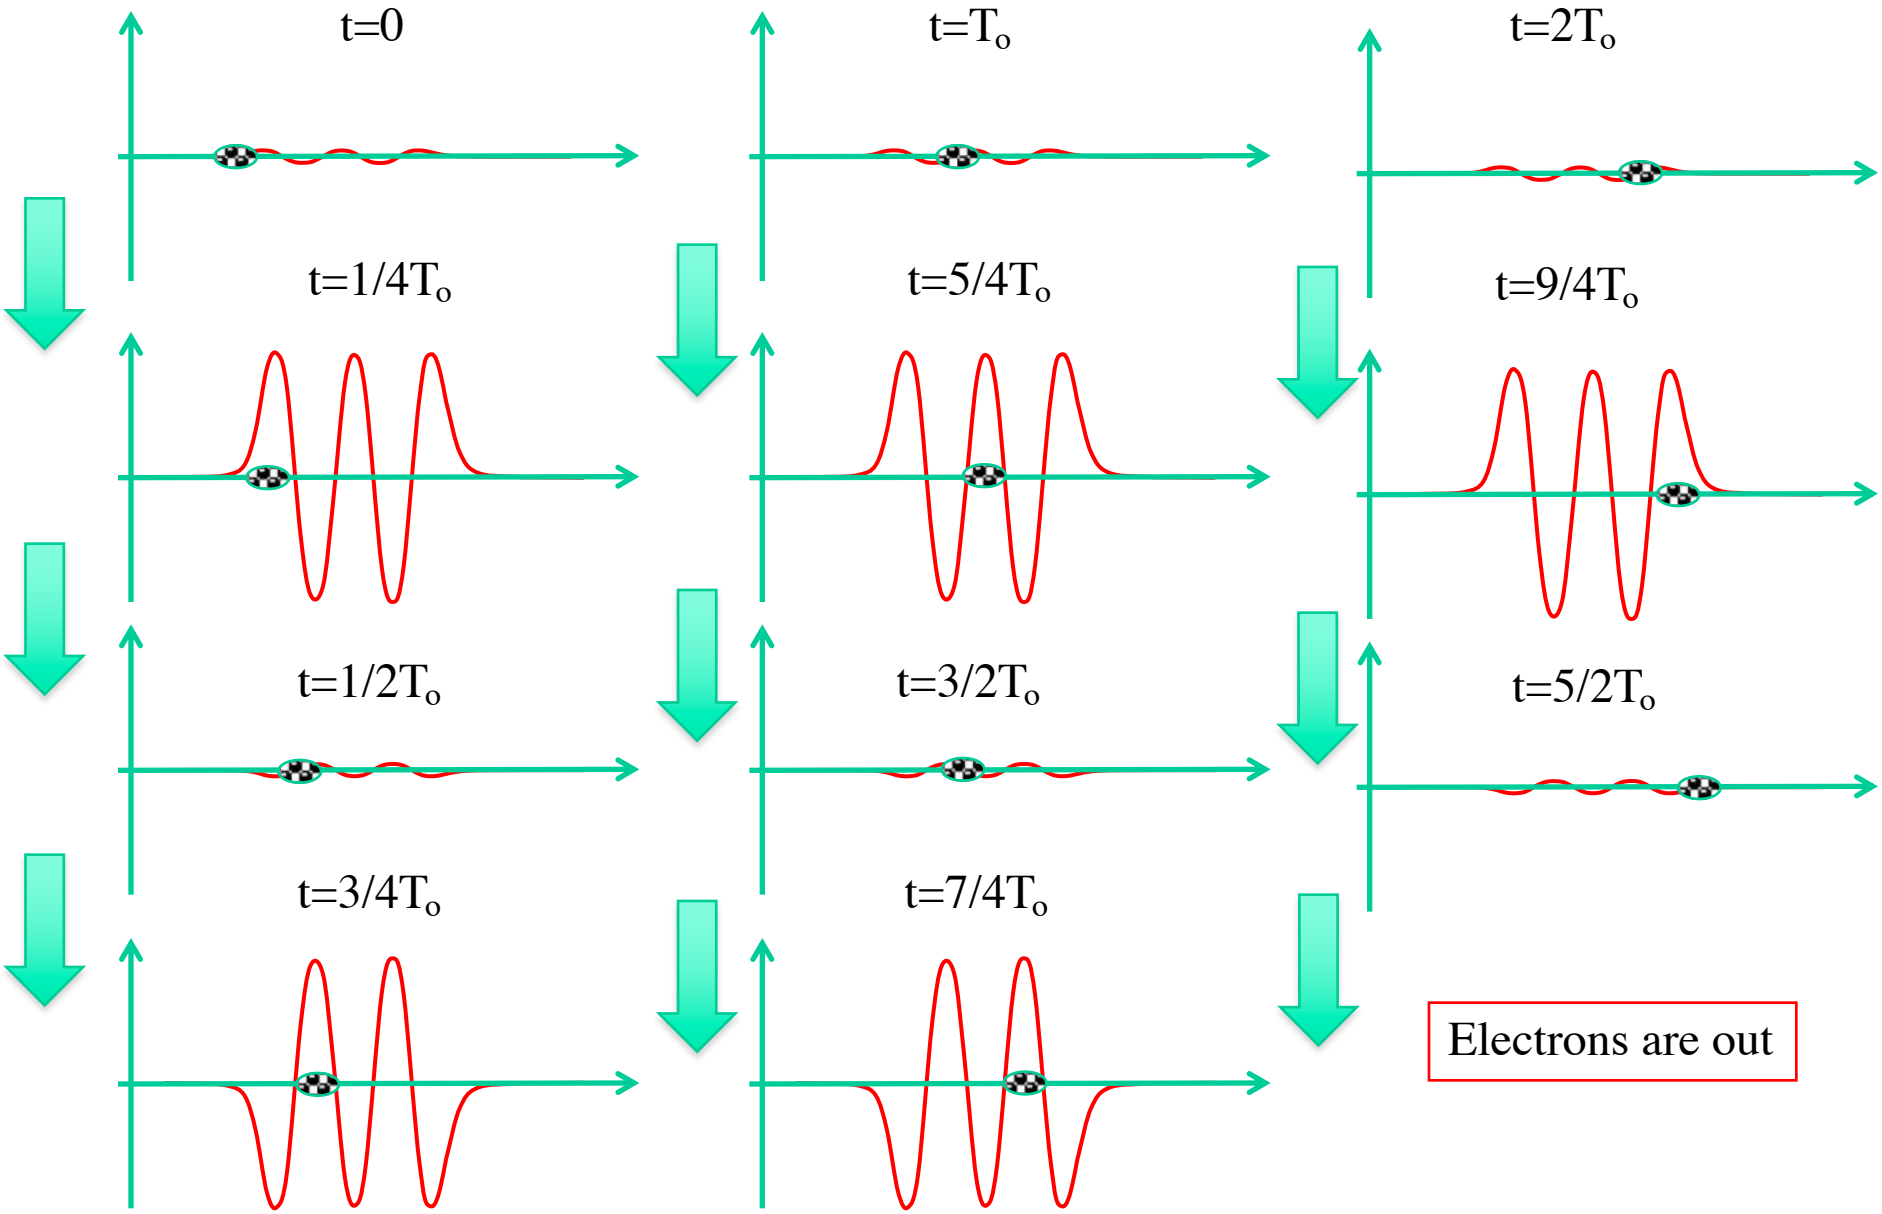


β=v/c ~1

Wave-form in 5-cell cavity



How β=1 RF linac works?
Example of 5-cell cavity



Simple things to remember

- Acceleration in DC electrostatic is limited to the difference in terminal potential (e.g. voltage between the ground and the cathode)
- RF linear accelerators (RF linacs or simply linacs) are not limited in beam energy
- In RF linacs, the coherent addition/subtraction of the energy gain from cell to cell happens by design: period of the electric field oscillation is matched to the travel time of electron between the cells.
- Accurate synchronization of RF linac is important task for any linear accelerator

A bit of EM and conducting media

$$\vec{j} = \sigma \vec{E};$$

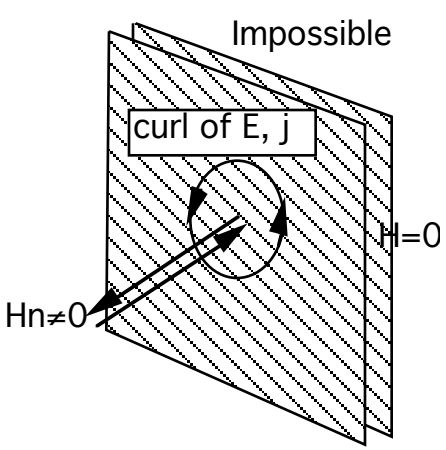
- Assuming oscillating field we can use Coulomb gauge for EM field

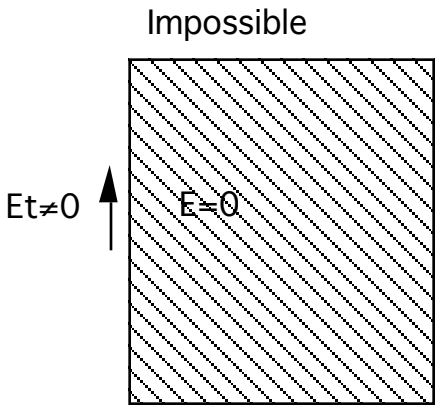
$$\vec{A} = \mathrm{Re}\left\{\vec{A}(\vec{r})\exp(i\omega t)\right\}; \varphi = 0;$$

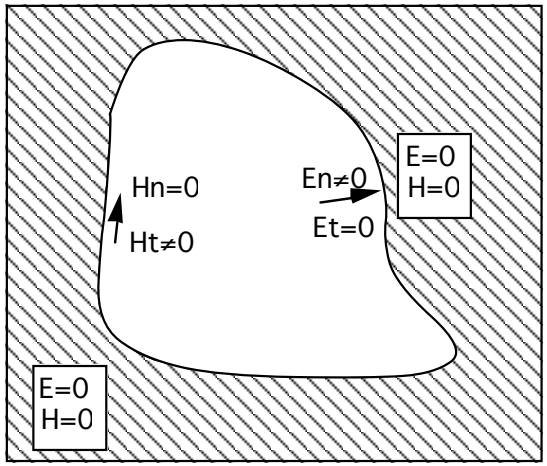
$$\vec{E} = -\frac{1}{c}\frac{\partial \vec{A}}{\partial t}; \quad \vec{B} = curl\vec{A}.$$

$$\left|\vec{H}\right| \propto \left|\frac{(\alpha + i\beta)}{k_o}\right|\left|\vec{E}\right| = \left|\sqrt{1 + \frac{4\pi i\sigma}{\omega}}\right|\left|\vec{E}\right|$$

$$\sigma \to \infty$$





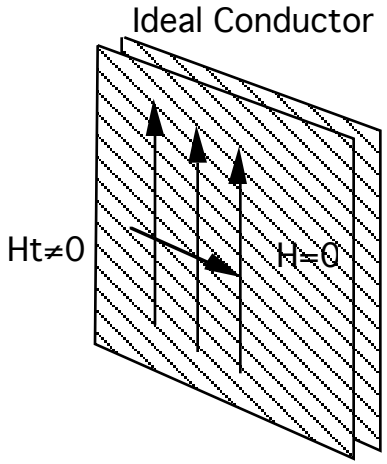


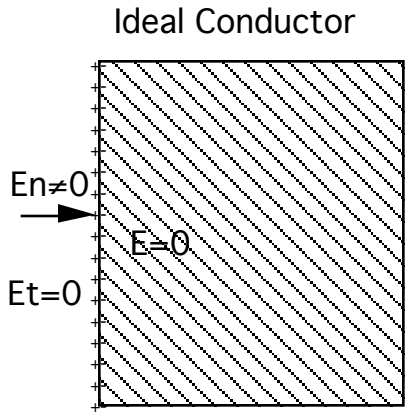
Boundary conditions

- We are considering oscillating EM fields in RF structures
- RF structures are built from highly conducting material, both to contain EM filed inside and to provide low losses
- In first approximation we can consider an ideal boundary conditions and take finite conductivty as a perturbation later
- Q-factor: $Q_{\text{room temp}} \sim 10^3\text{-}10^5$, $Q_{SRF} \sim 10^9\text{-}10^{10}$

$$\vec{A} = \mathrm{Re}\left\{\vec{A}(\vec{r})\exp(i\omega t - \alpha t)\right\};$$

$$\alpha = \frac{2\pi\omega}{Q}$$

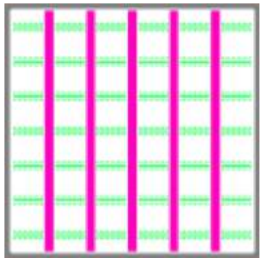


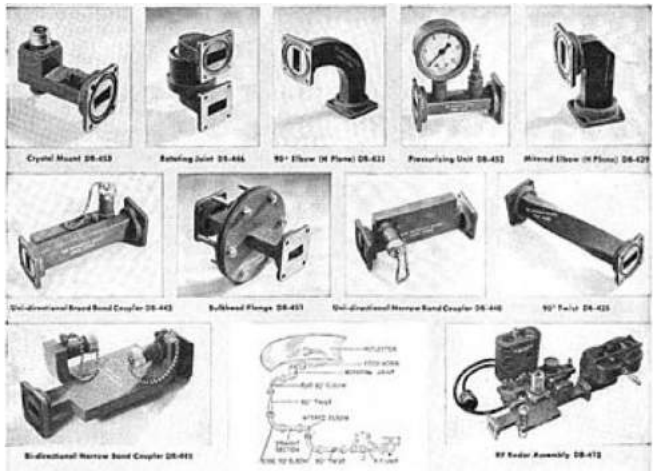


$$\vec{E} = \vec{n}\left(\vec{n}\vec{E}\right) + \vec{E}_{//}; \vec{B} = \vec{n}\left(\vec{n}\vec{B}\right) + \vec{B}_{//};$$

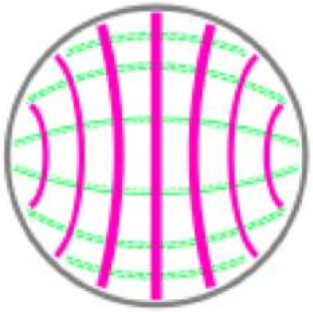
Waveguides

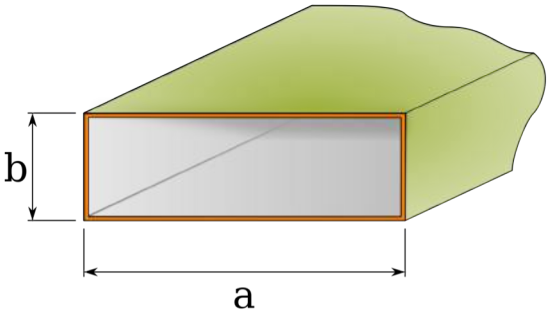
Rectangular





Circular



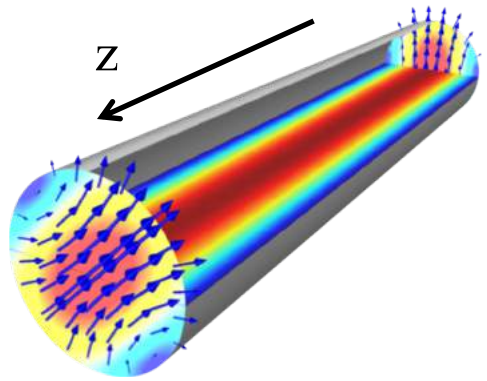


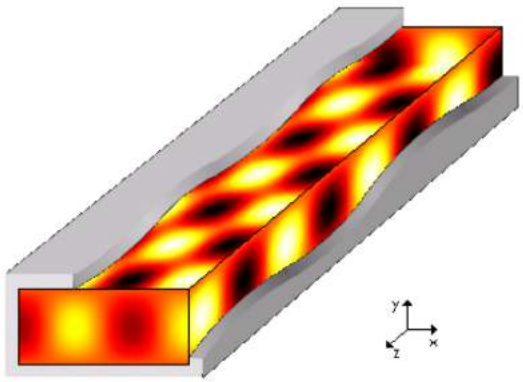
$$\left(\Delta - \frac{1}{c^2}\frac{\partial^2}{\partial t^2}\right)\vec{A} = 0;\ \ \Delta \equiv \vec{\nabla}^2 = \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial z^2};$$

$$\vec{A} = \mathrm{Re}\left\{\vec{A}(\vec{r}_\perp)\exp\left(i\left(\omega t - k_z z\right)\right)\right\};$$

$$\vec{\nabla}_\perp^2\vec{A} + \left(k_o^2 - k_z^2\right)\vec{A} = 0; \quad k_o = \frac{\omega}{c}.$$

$$\vec{\nabla}_\perp^2 \equiv \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} = \frac{1}{r}\frac{\partial}{\partial r}\left(r\frac{\partial}{\partial r}\right) + \frac{1}{r^2}\frac{\partial^2}{\partial \theta^2}.$$



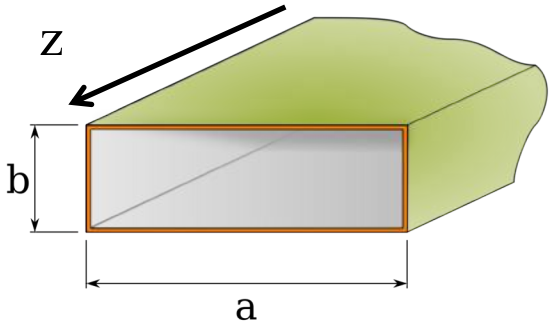


At the surfaces

$$\vec{n}\times\vec{E}\Big|_s = 0;\ \vec{n}\cdot\vec{B} = 0 \rightarrow E_z\Big|_s = 0;\ \frac{\partial B_z}{\partial n}\Big|_s = 0$$

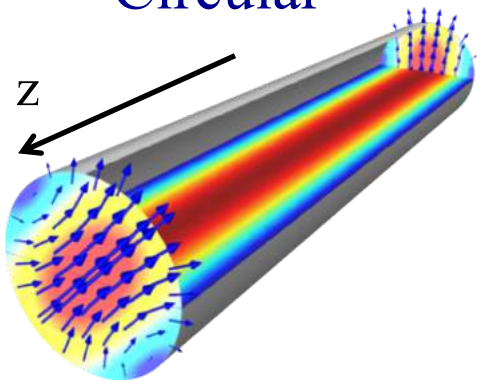
TE and TM waves

Rectangular



- There is simplification
  - The modes are divided into two types: TE (transverse electric) and TM (transverse magnetic)

Circular

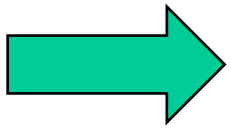


$$\vec{E} = \vec{E}_z + \vec{E}_\perp; \vec{B} = \vec{B}_z + \vec{B}_\perp; \ \vec{A}_z \equiv \hat{z}A_z;$$

$$\vec{\nabla} \times \vec{E} = ik_o\vec{B}; \ \vec{\nabla} \times \vec{B} = -ik_o\vec{E}; \ \Rightarrow$$

$$ik_z\vec{E}_\perp + ik_o\left[\hat{z} \times \vec{B}_\perp\right] = \vec{\nabla}_\perp E_z;$$

$$ik_z\vec{B}_\perp - ik_o\left[\hat{z} \times \vec{E}_\perp\right] = \vec{\nabla}_\perp B_z;$$



- Last two equations indicated that E_z and B_z fully determine transverse component of the EM field
- It means that we can always consider a linear combination of the fields with $E_z = 0$ *everywhere* (TE) and $B_z = 0$ *everywhere* (TM)
- Naturally, when we interested in accelerating particles, we will need TM mode with $E_z \neq 0$.

At the surfaces

$$\vec{n} \times \vec{E}\Big|_s = 0; \vec{n} \cdot \vec{B} = 0 \rightarrow E_z\Big|_s = 0; \ \frac{\partial B_z}{\partial n}\Big|_s = 0$$

$$TM: B_z \equiv 0; \ E_z\Big|_s = 0;$$

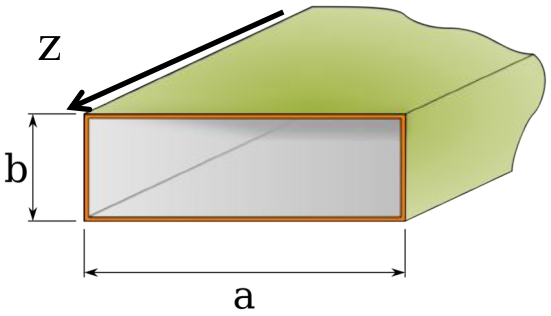
$$TE: E_z \equiv 0; \ B_z\Big|_s = 0;$$

$$\vec{B}_\perp = \pm\frac{k_z}{k_o}\left[\hat{z} \times \vec{E}_\perp\right] \text{ for both TE and TM modes}$$

TM: $\vec{E}_\perp = \vec{\nabla}_\perp \psi_1(\vec{r}_\perp)$; TE: $\vec{B}_\perp = \vec{\nabla}_\perp \psi_2(\vec{r}_\perp)$;

Cut-off frequency

Rectangular

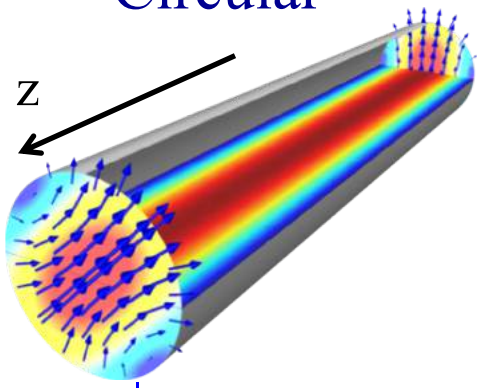


- EM field is a linear combination of modes with $E_z = 0$ *everywhere* (TE) and $B_z = 0$ *everywhere* (TM)

At the surfaces

$$\vec{n}\times\vec{E}\Big|_s = 0;\ \vec{n}\cdot\vec{B} = 0 \rightarrow E_z\Big|_s = 0;\ \frac{\partial B_z}{\partial n}\Big|_s = 0$$

Circular



$$\vec{B}_\perp = \pm\frac{k_z}{k_o}\left[\hat{z}\times\vec{E}_\perp\right]$$ for both TE and TM modes

$$TM: B_z \equiv 0;\ E_z\Big|_s = 0;$$

$$TE: E_z \equiv 0;\ B_z\Big|_s = 0;$$

TM: $\vec{E}_\perp = \vec{\nabla}_\perp\psi_1(\vec{r}_\perp);$ TE: $\vec{B}_\perp = \vec{\nabla}_\perp\psi_2(\vec{r}_\perp);$

$$TM: \psi\Big|_s = 0;\ TE: \frac{\partial\psi}{\partial n}\Big|_s = 0.$$

$$\vec{\nabla}_\perp^2\psi + \left(k_o^2 - k_z^2\right)\psi = 0 + \textit{boundary conditions}$$

$$\vec{\nabla}_\perp^2\psi_\lambda + \gamma_\lambda{}^2\psi_\lambda = 0;\quad \lambda = 1,2,3,\ldots$$

Different boundary conditions for TE and TM modes
In general case we need to find eigen function (modes)

Cut-off frequency

$$k_{z,\lambda}^2 = k_o^2 - \gamma_\lambda^2 > 0$$

$$k_{o\min} = \gamma_\lambda \rightarrow \omega_{cut-off} = c\gamma_\lambda$$

Below cut-off evanescent wave: Exp decay

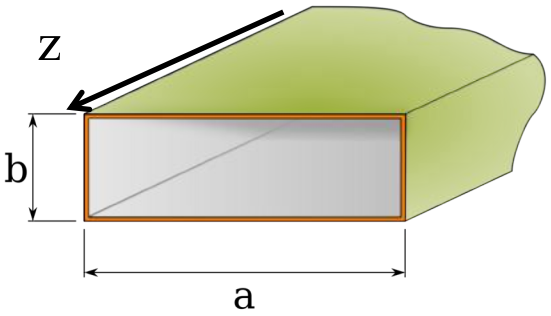
$$\omega < \omega_{cut-off}$$

$$k_z = \pm i\sqrt{\omega^2{}_{cut-off} - \omega^2} = \pm i\kappa_z$$

$$\psi = \psi_0 e^{\pm\kappa_z z}$$

Cut-off frequency

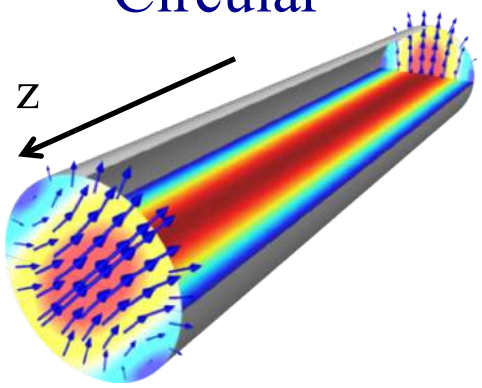
Rectangular



Different boundary conditions for TE and TM modes

$$TM: \psi\big|_s = 0;\ \ TE: \left.\frac{\partial \psi}{\partial n}\right|_s = 0.$$

Circular



$$\left(\frac{\partial^2}{\partial x^2}+\frac{\partial^2}{\partial y^2}\right)\psi+\gamma_{mn}^2\psi=0$$

$$TE:\psi^{TE}{}_{mn}=\psi_o\cos k_m x\cos k_n x;\ \ m+n\geq 1;$$

$$TM:\psi^{TM}{}_{mn}=\psi_o\sin k_m x\sin k_n x;\ \ m\geq 1; n\geq 1;$$

$$k_m=\pi\frac{m}{a}; k_m=\pi\frac{n}{b}; \gamma_{mn}=k_m{}^2+k_n{}^2.$$

$$\frac{1}{r}\frac{\partial}{\partial r}\left(r\frac{\partial\psi}{\partial r}\right)+\frac{1}{r^2}\frac{\partial^2\psi}{\partial\theta^2}+\gamma_{mn}^2\psi=0$$

$$\psi_{mn}=\varphi_{mn}(r)e^{in\theta}\Rightarrow r\frac{\partial}{\partial r}\left(r\frac{\partial\psi_m}{\partial r}\right)+\left(r^2\gamma_{mn}^2-n\right)=0$$

$$\varphi_{mn}=J_n(\gamma_{mn}r)$$

Lowes cut-off frequency

Rectangular

$$TE: a>b; m=1; n=0;\ \omega_{cut-off}=\frac{\pi c}{a};$$

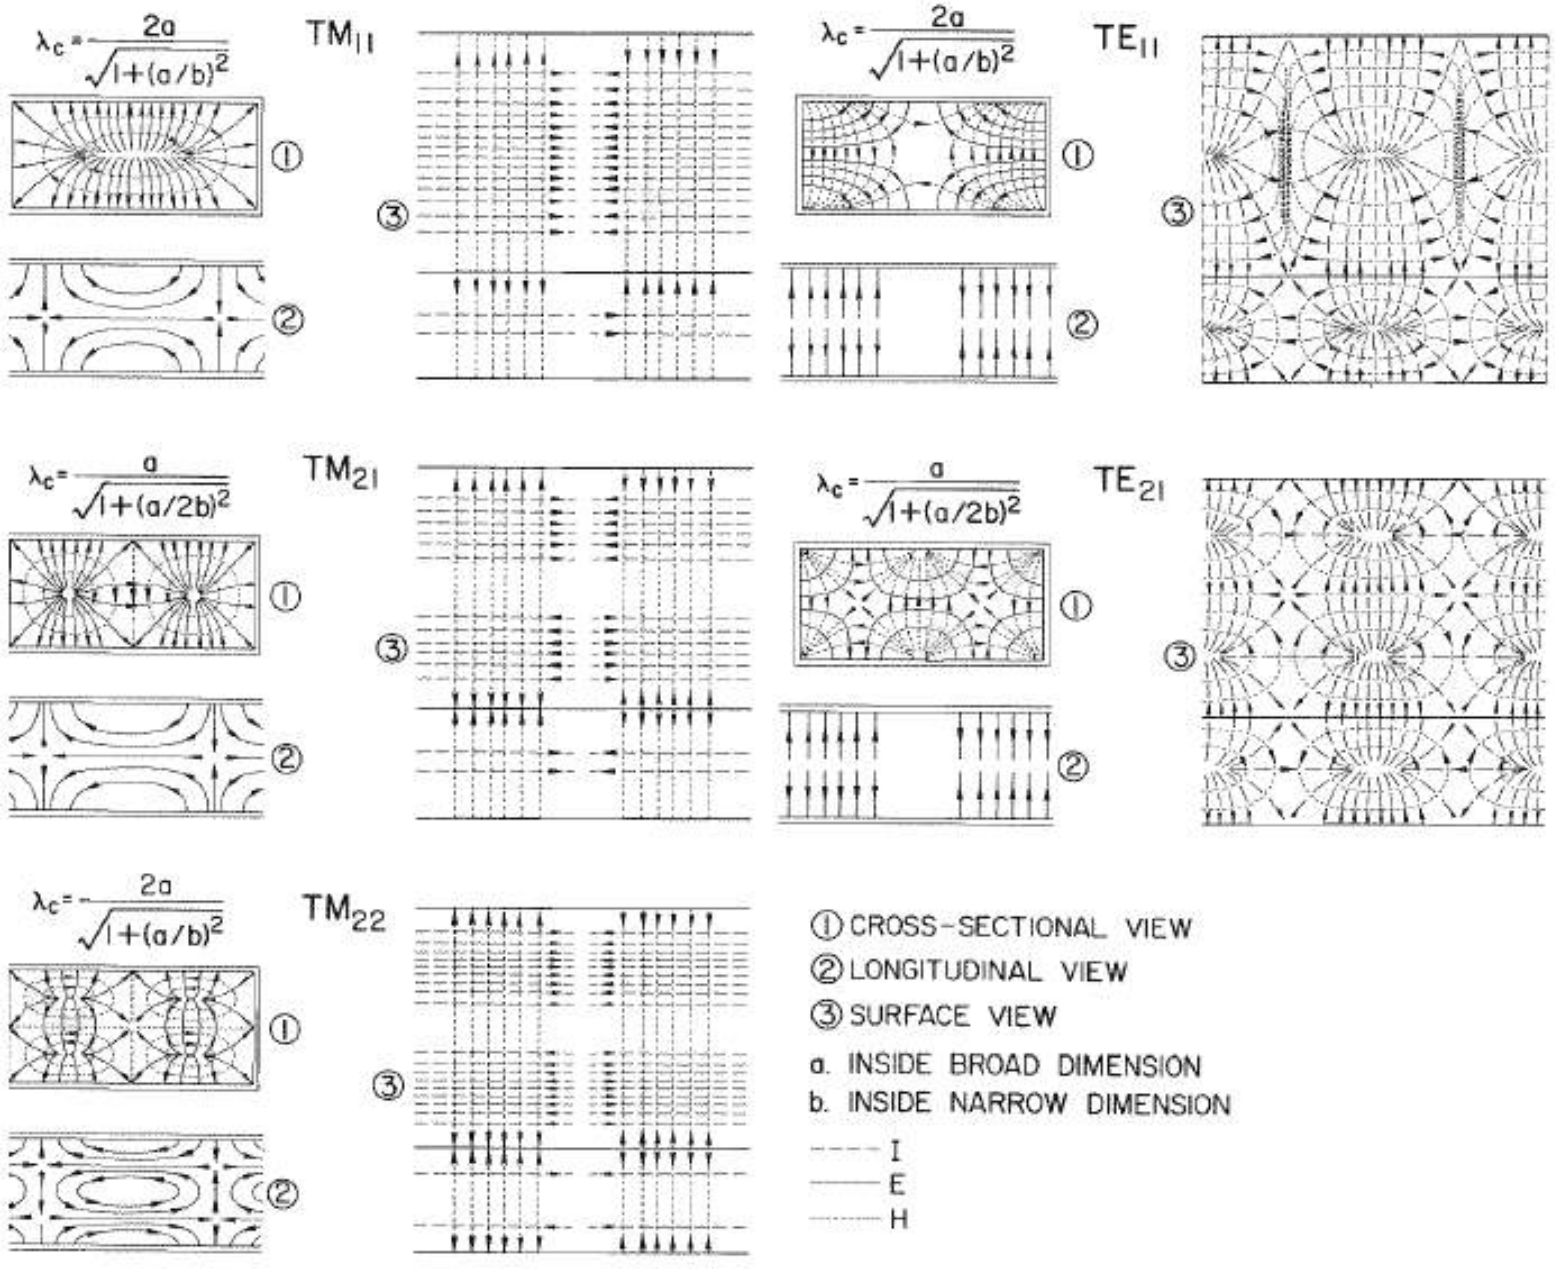
$$TM:\ m=1; n=1;\ \omega_{cut-off}=\frac{\pi c}{a}\sqrt{1+\frac{a^2}{b^2}}.$$

Circular

$$TM: J_o(\gamma_{01}R)=0\rightarrow\gamma_{01}\cong\frac{2.40483..}{R};\ \omega_{cut-off}\cong\frac{2.40\ c}{R};$$

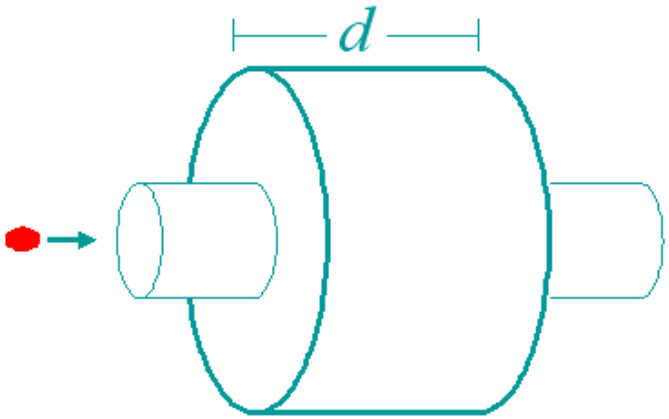
$$TE: J_1(\gamma_{11}R)=0\rightarrow\gamma_{11}\cong\frac{1.84118....}{R};\ \omega_{cut-off}\cong\frac{1.84\ c}{R}.$$

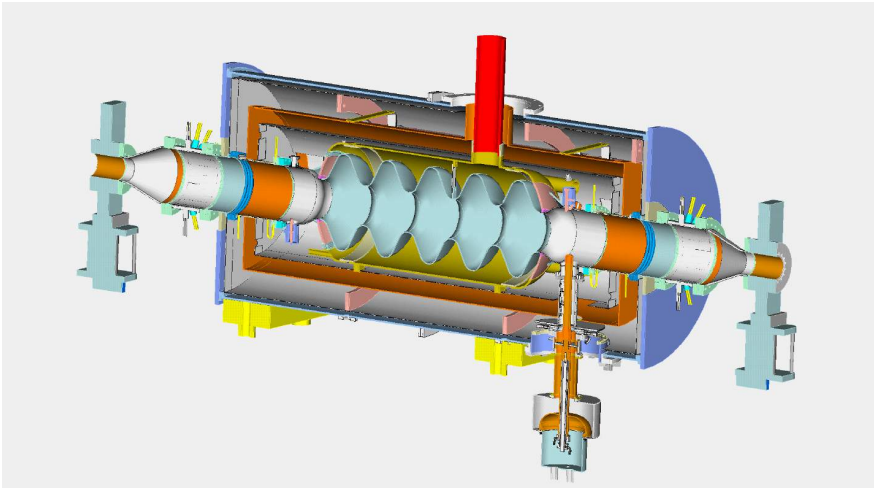
Modes in rectangular waveguide

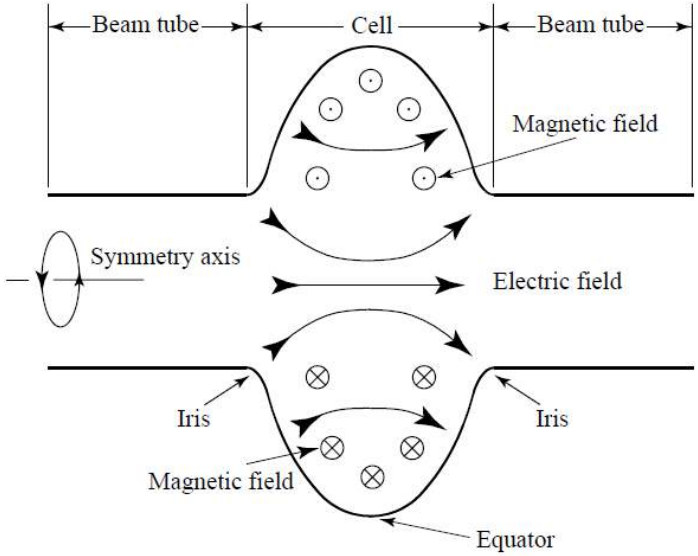


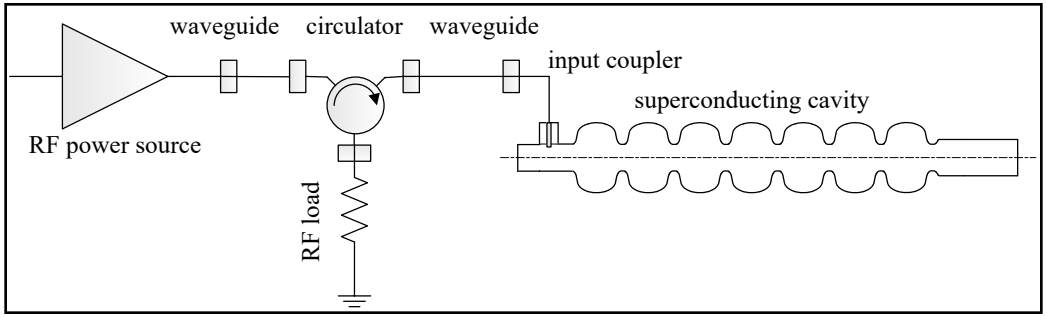
RF cavities

are designed to confine the EM field inside: It means that they operate at frequency below cut-off of the beam-pipes attached to them









RF Cavity Modes:

the lowest accelerating is TM_{010} mode

- Fields in the cavity are solutions of the equation
- Subject to the boundary conditions $\hat{n}\times\mathbf{E}=0,\ \hat{n}\cdot\mathbf{H}=0$
- Two extra surfaces (z=0 and z=d): but this is no problem for TM mode

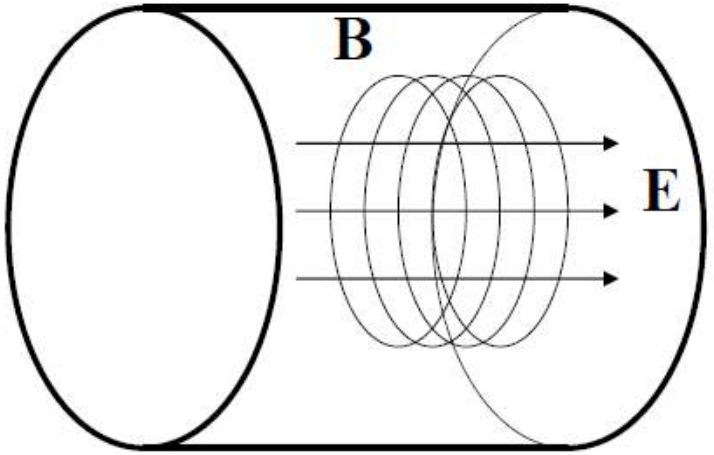
$$\left(\nabla^2-\frac{1}{c}\frac{\partial^2}{\partial t}\right)\begin{Bmatrix}\mathbf{E}\\ \mathbf{H}\end{Bmatrix}=0$$

- An infinite number of solutions (eigen modes) belong to two families of modes with different field structure and eigen frequencies: TE modes have only transverse electric fields, TM modes have only transverse magnetic fields.
- One needs longitudinal electric field for acceleration, hence the lowest frequency TM_{010} mode is used.
- For the pillbox cavity w/o beam tubes
- Note that frequency does not depend of the cavity length! But only its radius.

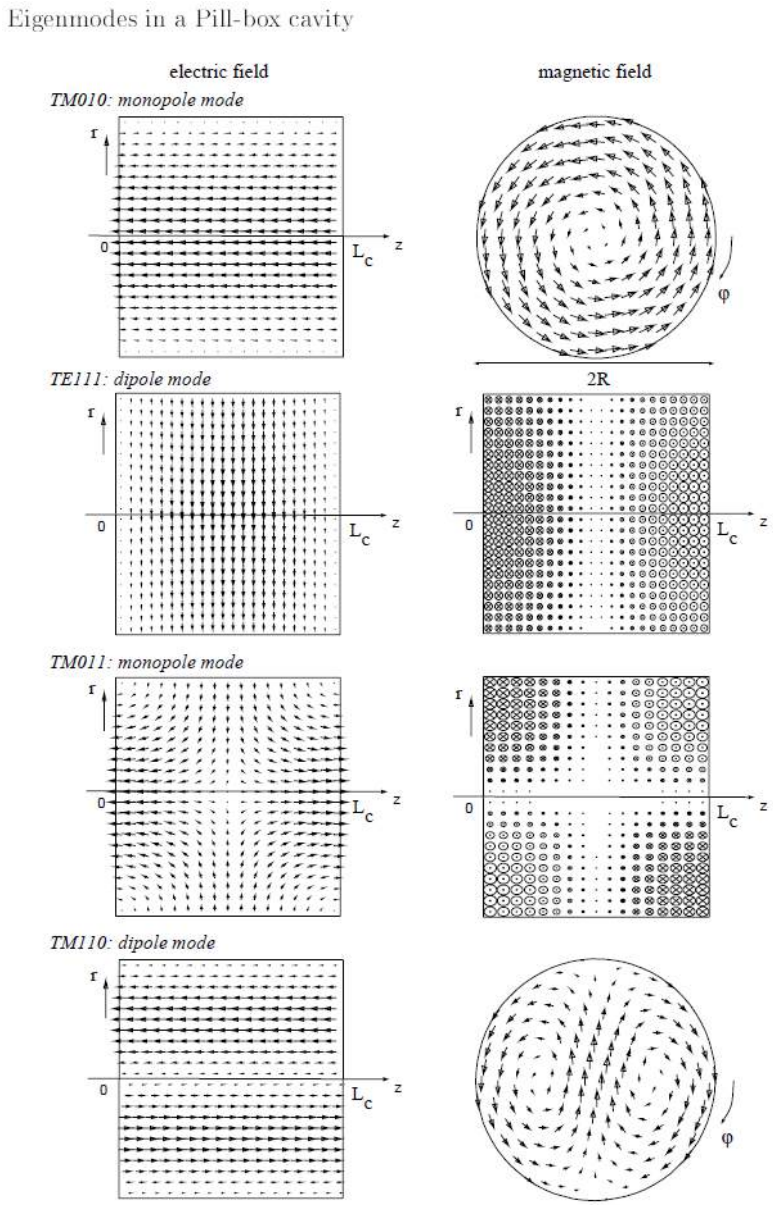
$$E_z=E_0J_0\left(\frac{2.405r}{R}\right)e^{i\omega t}$$

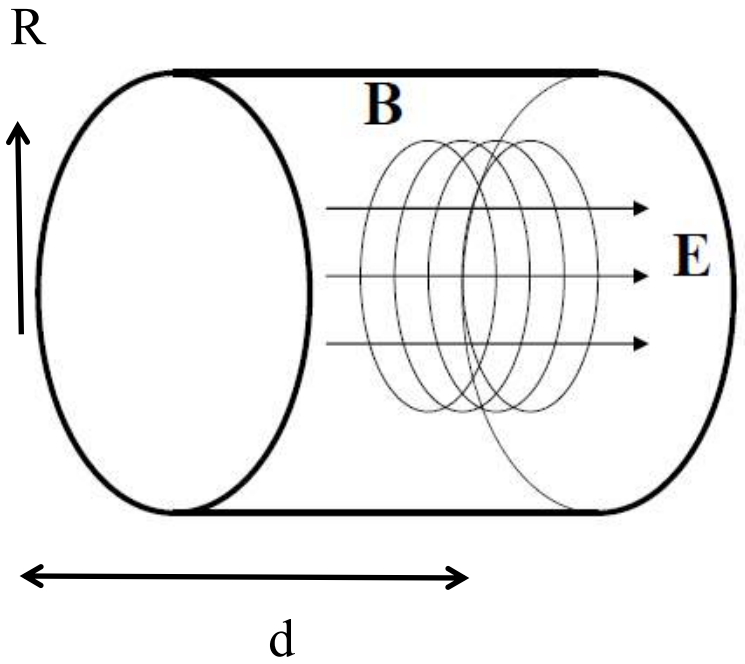
$$H_\phi=-iE_0J_1\left(\frac{2.405r}{R}\right)e^{i\omega t}$$

$$\omega_{010}=\frac{2.405c}{R},\ \lambda_{010}=2.61R$$



Fundamental and high order modes (HOMs)





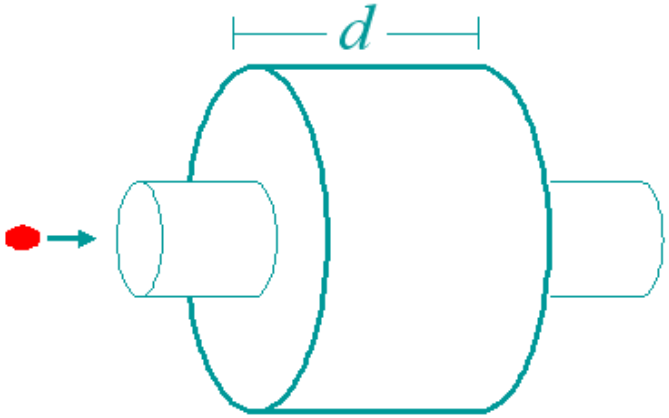
$$TM: \varphi_{mnl} = J_n(\gamma_{mn} r)\cos k_{z,l} z;\ k_{z,l} = l\frac{\pi}{d};\ J_n(\gamma_{mn} R) = 0;$$

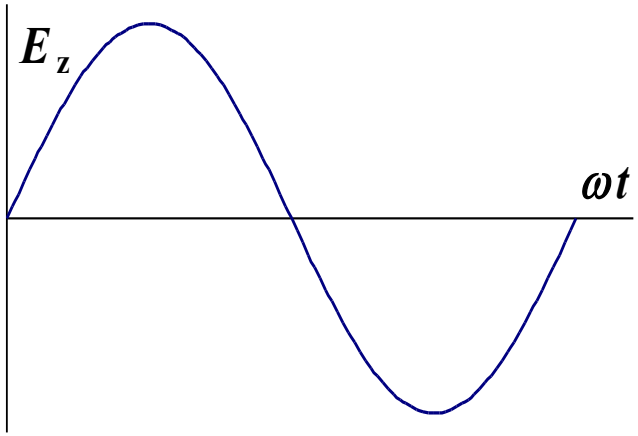
$$\omega_{res} = c\sqrt{\gamma_{mn}^2 + l^2\frac{\pi^2}{d^2}};\ l = 0,1,2....$$

$$TE: \varphi_{mnl} = J_n(\kappa_{mn} r)\sin k_{z,l} z;\ k_{z,l} = l\frac{\pi}{d};\ J_n'(\kappa_{mn} R) = 0;$$

$$\omega_{res} = c\sqrt{\kappa_{mn}^2 + l^2\frac{\pi^2}{d^2}};\ l = 1,2....$$

Accelerating voltage & transit time





- Assuming charged particles moving along the cavity axis, one can calculate accelerating voltage as

$$V_c = \left| \int_{-\infty}^{\infty} E_z(\rho = 0, z) e^{i\omega_0 z/\beta c} dz \right|$$

For the pillbox cavity one can integrate this analytically:

$$V_c = E_0 \left| \int_0^d e^{i\omega_0 z/\beta c} dz \right| = E_0 d \frac{\sin\left(\frac{\omega_0 d}{2\beta c}\right)}{\frac{\omega_0 d}{2\beta c}} = E_0 d \cdot T$$

where T is the transit time factor.

- To get maximum acceleration:

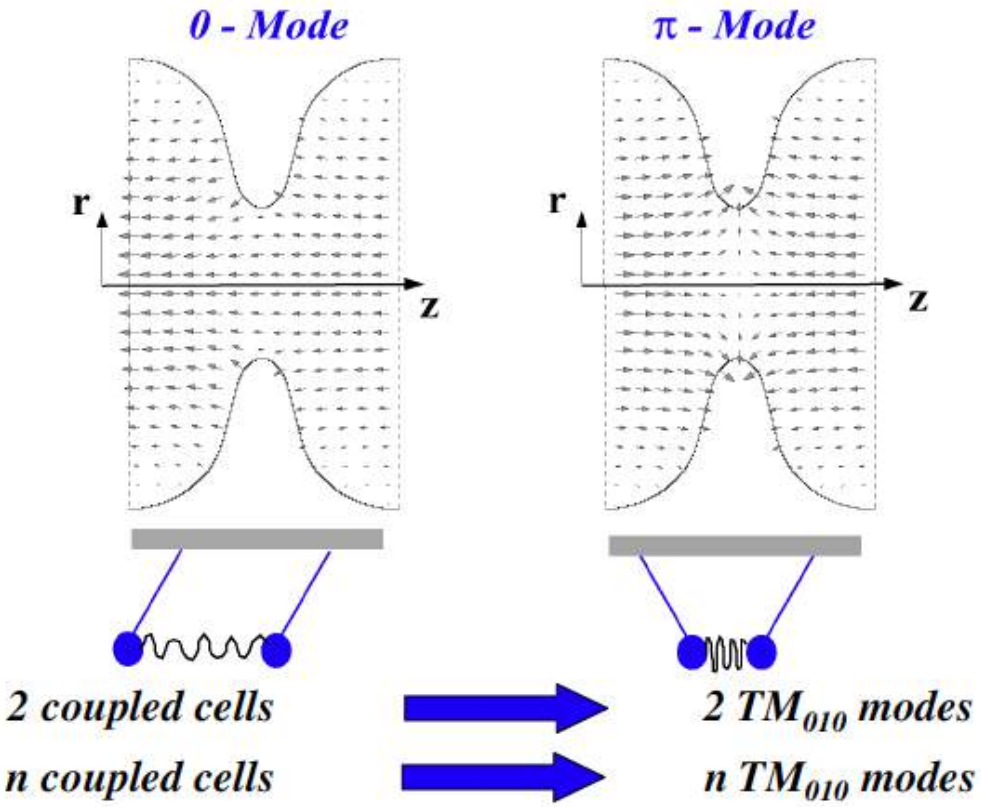
$$T_{transit} = t_{exit} - t_{enter} = \frac{T_0}{2} \Rightarrow d = \beta\lambda/2 \Rightarrow \quad V_c = \frac{2}{\pi} E_0 d$$

Thus for the pillbox cavity $T = 2/\pi$.

- The accelerating field E_{acc} is defined as $E_{acc} = V_c/d$. Unfortunately the cavity length is not easy to specify for shapes other than pillbox so usually it is assumed to be $d = \beta\lambda/2$. This works OK for multi-cell cavities, but poorly for single-cell ones.

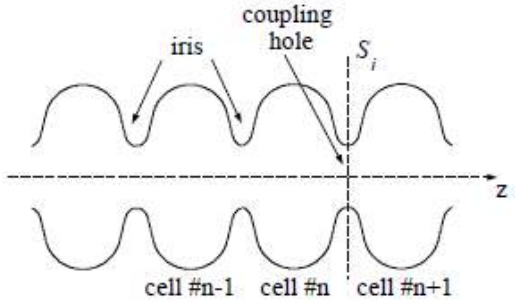
Multicell cavities: coupled oscillators

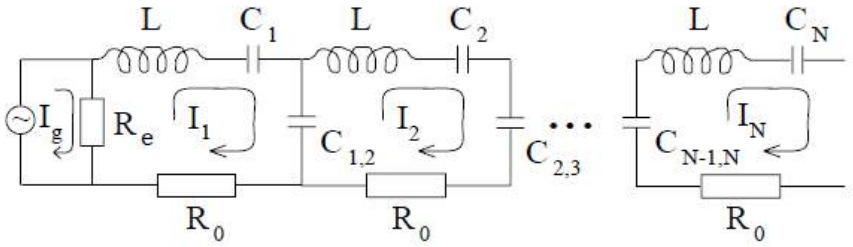
- Several cells can be connected together to form a multicell cavity.
- Coupling of TM_{010} modes of the individual cells via the iris (primarily electric field) causes them to split:



Multicell cavities (2)

- The split mode forms a passband of closely spaced modes equal in number to the number of cells.

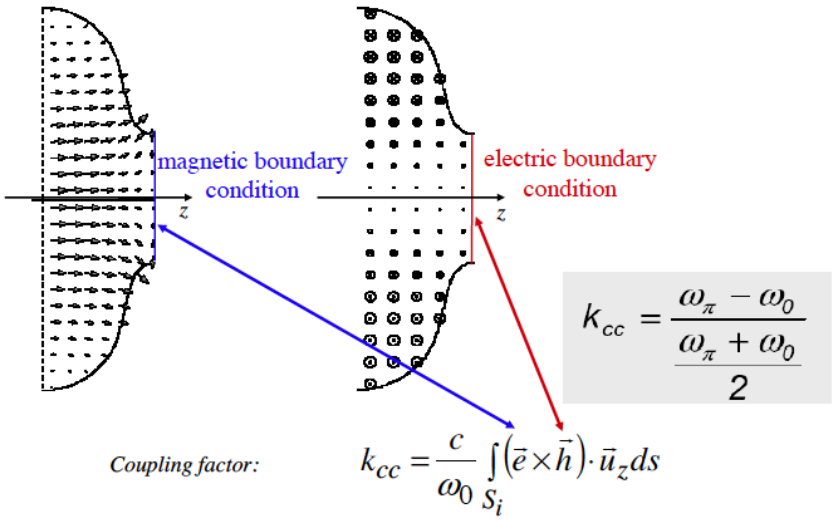




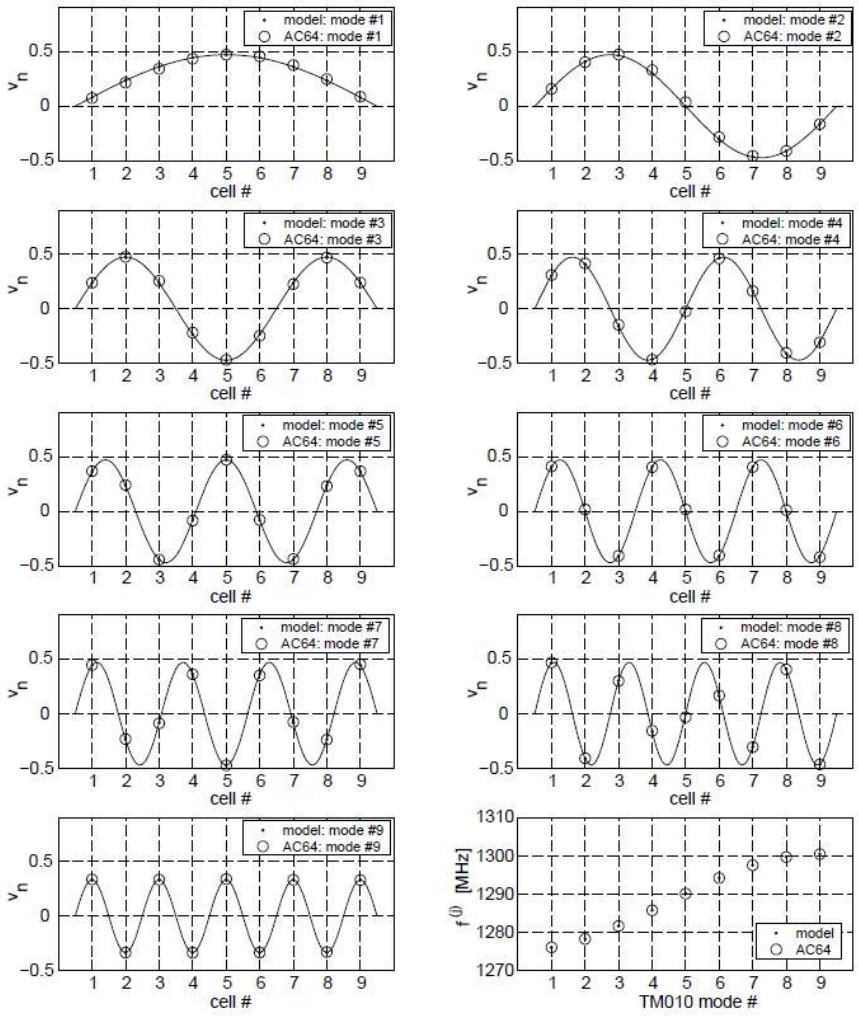
- The ned by frequency of the *n*-th mode can be calculated from the dispersion formula

$$\left(\frac{f_n}{f_0}\right)^2 = 1 + 2k\left[1 - \cos\left(\frac{n\pi}{N}\right)\right]$$

where N is the number of cells,
$n = 1 \ldots N$ is the mode number.



Multicell cavities (2)



- Figure shows an example of calculated eigenmodes amplitudes in a 9-cell TESLA cavity compared to the measured amplitude profiles. Also shown are the calculated and measured eigenfrequencies.
- A longer cavity with more cells has more modes in the same frequency range, hence the reduction in frequency difference between adjacent modes. The number of cells is usually a result of the accelerating structure optimization.
- The accelerating mode for SC cavities is usually the **p**-mode, which has the highest frequency for electrically coupled structures.
- The same considerations are true for HOMs.

What we learned

- Resonant modes in a cavity resonator belong to two families: TE and TM.
- There is an infinite number of resonant modes.
- The lowest frequency TM mode is usually used for acceleration.
- All other modes (HOMs) are considered parasitic as they can harm the beam.
- Several figures of merits are used to characterize accelerating cavities: main are accelerating voltage, transit time and Q-factor.
- In a multi-cell cavity every mode splits into a pass-band.
- The number of modes in each pass-band is equal to the number of cavity cells.
- The width of the pass-band is determined by the cell-to-cell coupling.
- Accelerating cavities operate at frequency below the cut-off frequency of vacuum pipes connected to them. The RF field decay exponentially along the pipes and reduces to a negligible level at length ~ few beam-pipe radii (assuming $R << \lambda_{RF}$)
- Coaxial lines and rectangular waveguides are commonly used in RF systems for power delivery to cavities

- Homework is posted on the website this evening: due in one week, October 3
